Practical – IV

Roll No.:T007	Name:Subhashree Jena
Class:TYIT	Batch:2
Date of Assignment: 25/07/26	Date/Time of Submission:25/07/26

Aim:-Write a Python program to compute the probability that the person actually has the disease given that the test result is positive.

Scenario:

A medical test is used to detect a particular disease.

The probability that a randomly selected person has the disease is 1%.

If a person has the disease, the test returns positive with probability 99%.

If a person does not have the disease, the test still returns positive with probability 5% (false positive rate).

A person takes the test and receives a positive result.

Code:-

```
# Probability of having disease
```

```
P_D = 0.01
```

```
# Probability of positive test if disease exists
```

```
P_Pos_D = 0.99
```

```
# Probability of positive test if disease does not exist
```

```
P_Pos_NotD = 0.05
```

```
# Probability of not having disease
```

```
P_NotD = 1 - P_D
```

```
# Bayes Rule
```

```
P_D_Pos = (P_Pos_D * P_D) / ((P_Pos_D * P_D) + (P_Pos_NotD * P_NotD))
```

```
print("Probability that person actually has disease:")
```

```
print(round(P_D_Pos * 100, 2), "%")
```

```
print("Subhashree Jena")
```

Output:-

```
Probability that person actually has disease:
16.67 %
Subhashree Jena
```
